Multiple Regression

Last time

Semi-partial and partial correlations

Today

Introduction to multiple regression

Regression equation

$$\hat{Y} = b_0 + b_1 X_1 + b_2 X_2 + \dots + b_k X_k$$

- regression coefficients are "partial" regression coefficients
 - \circ predicted change in Y for a 1 unit change in X, holding all other predictors constant
 - \circ similar to semi-partial correlation -- represents part of each X

Interpretting multiple regression model

$$\hat{Y} = b_0 + b_1 X_1 + b_2 X_2 + \dots + b_k X_k$$

- Intercept is the value of Y when all predictors = 0
- ullet Regression coefficients are the predicted change in Y for a 1 unit change in X, holding all other predictors constant

Interpretting multiple regression model

$$\hat{Y} = b_0 + b_1 X_1 + b_2 X_2 + \dots + b_k X_k$$

- ullet Residual in simple regression can be thought of as a measure of Y that is left over after accounting for your DV
- Partial correlation can be created by:
 - 1. create a measure of X_1 that is independent of X_2
 - 2. create a measure of Y that is independent of X_2
 - 3. correlate the new measures

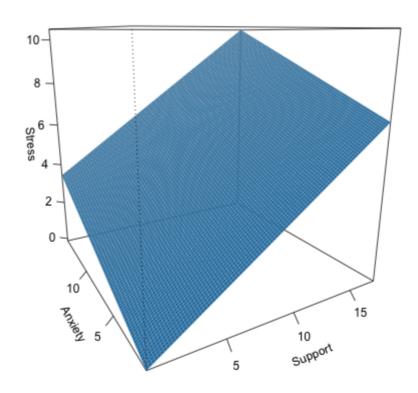

Example

```
library(here)
stress.data = read.csv(here("data/stress.csv"))
library(psych)
describe(stress.data$Stress)
```

Example

```
mr.model <- lm(Stress ~ Support + Anxiety, data = stress.data
summary(mr.model)
```

Visualizing multiple regression

Calculating coefficients

Just like with univariate regression, we calculate the OLS solution. As a reminder, this calculation will yield the estimate that reduces the sum of the squared deviations from the line:

Unstandardized

$$\hat{Y}=b_0+b_1X1+b_2X_2$$

minimize
$$\sum (Y - \hat{Y})^2$$

Standardized

$$\hat{Z}_Y = b_1^* Z_{X1} + b_2^* Z_{X2}$$

$$\text{minimize} \sum (Y - \hat{Y})^2 \qquad \text{minimize} \sum (z_Y - \hat{z}_Y)^2$$

Calculating the standardized partial regression coefficient

$$b_1^* = rac{r_{Y1} - r_{Y2} r_{12}}{1 - r_{12}^2}$$

$$b_2^* = rac{r_{Y2} - r_{Y1}r_{12}}{1 - r_{12}^2}$$

Notice the similarity with semipartial correlation

$$b_1^* = rac{r_{Y1} - r_{Y2} r_{12}}{1 - r_{12}^2}$$

$$sr = r_{y(1.2)} = rac{r_{Y1} - r_{Y2}r_{Y12}}{\sqrt{1 - r_{12}^2}}$$

Relationships between partial, semi- and b*

All ways to represent the relationship between two variables while taking into account a third (or more!) variables.

• Each is a standardized effect, bounded by -1 and 1*. This means they can be compared.

Not equal calculations!

ullet If predictors are not correlated, r, sr $(r_{Y(1.2)})$ and b* are equal

*Standardized regression coefficients are not bounded by

-1 and 1, but it's rare and usually a problem

Standardized mult regression coefficient b^st

$$rac{r_{Y1}-r_{Y2}r_{12}}{1-r_{12}^2}$$

Semi-partial correlation $r_{y(1.2)}$

$$rac{r_{Y1}-r_{Y2}r_{Y12}}{\sqrt{1-r_{12}^2}}$$

Partial correlation $r_{y1.2}$

$$rac{r_{Y1}-r_{Y2}r_{12}}{\sqrt{1-r_{Y2}^2}\sqrt{1-r_{12}^2}}$$

```
mod0 = lm(z_stress ~ z_anxiety + z_support,
          data = stress.data)
round(coef(mod0),3)
## (Intercept) z_anxiety z_support
        0.000 0.339 0.710
##
                                pcor.test(x = stress.data$An)
spcor.test(x = stress.data$Ai
           y = stress.data$S
                                          y = stress.data$St
           z = stress.data$Si
                                          z = stress.data$Su
## [1] 0.2797712
                               ## [1] 0.3339479
```

They're not the same, but they're close!

Review

Original Metric

$$b_1=b_1^*rac{s_Y}{s_{X1}}$$

$$b_1^*=b_1rac{s_{X1}}{s_Y}$$

Intercept

$$b_0 = \bar{Y} - b_1 \bar{X}_1 - b_2 \bar{X}_2$$

```

```

Multiple correlation, R

$$\hat{Y} = b_0 + b_1 X_1 + b_2 X_2$$

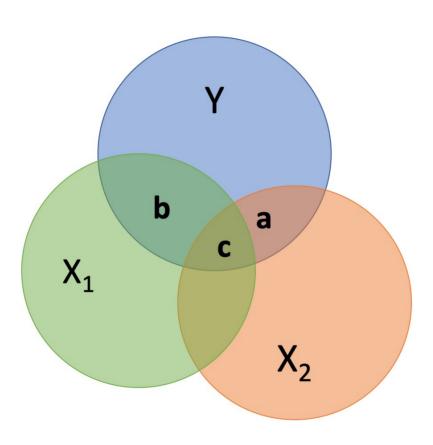

- ullet \hat{Y} is a linear combination of Xs
- $r_{Y\hat{Y}}$ = multiple correlation = R

$$R = \sqrt{b_1^* r_{Y1} + b_2^* r_{Y2}}$$

$$R^2 = b_1^* r_{Y1} + b_2^* r_{Y2}$$

$$R_{Y.12}^2 = b_{Y1.2}^* r_{Y1} + b_{Y2.1}^* r_{Y2}$$

Decomposing sums of squares

We haven't changed our method of decomposing variance from the univariate model

$$rac{SS_{regression}}{SS_{Y}}=R^{2}$$

$$SS_{regression} = R^2(SS_Y)$$

$$SS_{residual} = (1 - R^2)SS_Y$$

Significance tests

- R^2 (omnibus)
- Regression Coefficients
- ullet Increments to R^2

R-squared, \mathbb{R}^2

- Same interpretation as before
- Adding predictors into your model will increase \mathbb{R}^2 regardless of whether or not the predictor is significantly correlated with Y.
- ullet Adjusted/Shrunken R^2 takes into account the number of predictors in your model

Adjusted R-squared, $\mathrm{Adj}R^2$

$$R_A^2 = 1 - rac{Var_{res}}{Var_{total}}$$

$$R_A^2 = 1 - rac{rac{SS_{res}}{n-p-1}}{rac{SS_{total}}{n-1}}$$

$$R_A^2 = 1 - (1 - R^2) \frac{n - 1}{n - p - 1}$$

Adjusted R-squared, $\mathrm{Adj}R^2$

$$R_A^2 = 1 - (1 - R^2) \frac{n - 1}{n - p - 1}$$

- What happens if you add many IV's to your model that are uncorrelated with your DV?
- What happens as you add more covariates to your model that are highly correlated with your key predictor, X?

$$b_1^* = rac{r_{Y1} - r_{Y2}r_{12}}{1 - r_{12}^2}$$

ANOVA

Test of individual regression coefficients

$$H_0: eta_X = 0$$

$$H_1:eta_X
eq 0$$

Test of individual regression coefficients

In the case of univariate regression:

$$se_b = rac{s_Y}{s_X} \sqrt{rac{1-r_{xy}^2}{n-2}}$$

In the case of multiple regression:

$$se_b = rac{s_Y}{s_X} \sqrt{rac{1 - R_{Y\hat{Y}}^2}{n - p - 1}} \sqrt{rac{1}{1 - R_{i.jkl...p}^2}}$$

- As N increases...
- As variance explained increases...
